

# Lunar Impact Glasses: Small Samples, Big Science

*Nicolle Zellner*  
*Albion College*

# Lunar Impact Glasses

Glasses are formed when regolith is melted during a high-temperature event  
→ where, when, how often impacts occurred

Glasses are small, “clean”, numerous, and optically homogeneous

**Motivation:** gain information about *regolith lithologies* AND the *lunar impact flux*

# Motivation: Lunar Lithologies

lunar impact glasses = melted regoliths

e.g., Chao et al. (1970); Glass (1971); Delano and Livi (1981); Delano (1986); Wentworth and McKay (1991); Zellner et al. (2002); Korotev et al. (2010); Huang et al. (2017)

## Compositions:

Regolith Transport

Subsurface material

Ancient regoliths

“Grab & Go” samples

Ratios of refractory elements: regoliths & glasses (Zellner, in review)

# Impact Glasses: Lunar Lithologies

***Powerful tools to extract info about lunar materials***

# Motivation: Impact Flux

ages of lunar impact glasses = timing of impact flux

e.g., Culler et al. (2000); Levine et al. (2005); Delano et al. (2007); Zellner et al. (2009a,b); Hui (2012); Norman et al. (2012); Nemchin et al. (2013); Zellner and Delano (2015); Zellner (2017); Huang et al. (2018); Zellner (in review); Norman et al. (in review)

$^{40}\text{Ar}/^{39}\text{Ar}$

U-Th-Pb

U-Pb

Composition

Spheres vs. Shards

Size

Delano *et al.* (2007): 1 large distant impact produces 4 glass shards w/ same age

# Motivation: Impact Flux

# Not All Impact Glasses Are The Same

Ar diffusivity:

Need to  
consider  
size, shape,  
X(NBO),  
K<sub>2</sub>O (wt%)  
and quality  
of age data

(Zellner and Delano, 2015;  
Nguyen and Zellner, 2019)

$^{40}\text{Ar}/^{39}\text{Ar}$  age “quality” affects usefulness of interpretation

# Consider Composition + Size

~120 glasses: cutoff size  $\geq 200 \mu\text{m}$  and X(NBO) value  $\geq 0.23$

Nguyen and Zellner (2019)

Bivariate density plots of size and X(NBO): Darker shading shows higher spatial density of glasses and indicates which values are more likely to yield “good” ages

# Consider Shape: Spherules vs. Shards

Reports of young  $^{40}\text{Ar}/^{39}\text{Ar}$  ages, Pb/Pb model ages, & U–Th–Pb chemical ages on glass *spherules*

(e.g., Culler et al. 2000, Levine et al. 2005, Adena et al. 2009, Hui, 2012

Norman et al. 2012, Nemchin et al. 2013 Norman et al., in review)

Spheres at ages  $\leq 1000$  Ma are common  
Spheres at ages  $\geq 1500$  Ma are rare

# Spherules: A Sampling Bias

## CTEM Model: A

preponderance of young sample ages is seen when

- the simulated impact depth is as shallow as 10 cm
- ejecta is beyond 10 radii from a crater

Huang *et al.*, 2018

## Conclusion:

Age record of lunar impact glass *spherules* may be due to a limited sampling depth and/or Ar diffusion

# Motivation: Impact Flux

# Future Work

Zellner (in review)

- Paleomagnetism

Determine what  
is significant

3730 Ma?

~600 Ma?

Find source craters

Trace elements

High-res orbital

data

Solar Wind

# Apollo 16 Drive Tube, 68001/2

Sample 1107, ~40 cm depth

Comps: Likely to yield very good Ar isotope data

# Apollo 16 Glasses

Range of ages seen in 64501, 66041 surface impact glasses

# Conclusions: Transformative Science

Impact glasses are useful tools for understanding

- the Moon's current, ancient, and subsurface lithologies and
- the Moon's impact history, especially when interpreted in the context of lunar (and other) impact samples

Impact glasses = “Grab & Go” samples

- abundant in any lunar regolith
- should be abundant in regoliths of other planetary bodies

# Conclusions

The accuracy and reliability of  $^{40}\text{Ar}/^{39}\text{Ar}$  ages are related to size, shape, composition, and CRE age.

→ Glasses with highlands compositions are unlikely to yield old ages.

→ Spheres have lifetimes  $\leq 1000$  Ma before being broken into shards.

Impact glasses with ages  $> 3500$  Ma, from the tail end of the late heavy bombardment, are preserved.

Shards may be the preferred sample shape.

# The Impact Flux

Ways to determine the time-varying impact flux:

Samples:

- crystalline melts in Apollo samples
- crystalline melt clasts in meteorites
- zircons
- lunar impact glasses

10s  $\mu\text{m}$

Other:

- crater counting and stratigraphy

~200  $\mu\text{m}$

# Impact Glasses: Lunar Lithologies

Delano *et al.* (2007): 1 large distant impact produces 4 glass shards w/ same age

Zellner *et al.* (2009): Variety of impact glass compositions

**Powerful tools to extract info about lunar materials**

# Not All Impact Glasses Are The Same

Ar diffusivity:

Need to  
consider  
size, shape,  
X(NBO),  
K<sub>2</sub>O (wt%)  
and quality  
of age data

(Nguyen and Zellner, 2019)

$^{40}\text{Ar}/^{39}\text{Ar}$  age “quality” affects usefulness of interpretation

# Case Study: ~800 Myo Impact Glasses

15 samples, 4 landing sites  
Multiple compositions

Revisited 2009 study:  
Evaluated samples  
for size, shape,  
X(NBO), &  
quality of age data

# 800 Myo Glasses: Copernicus?

Probably not (& ~800 Ma ages in other samples + craters)

# Case 1: Impact Glasses $\geq 3500$ Myo

| Sample Number | Age $\pm 2\sigma$ (Ma) | Shape  | X(NBO) | Quality of Age Plot |
|---------------|------------------------|--------|--------|---------------------|
| 293           | $3740 \pm 50$          | shard  | 0.27   | good                |
| 369           | $3630 \pm 40$          | shard  | 0.38   | good                |
| 390           | $3580 \pm 45$          | shard  | 0.25   | good                |
| 375           | $3475 \pm 452$         | shard  | 0.26   | fair                |
| 393           | $3316 \pm 1198$        | sphere | 0.29   | fair                |
| 382           | $2960 \pm 1600$        | shard  | 0.24   | fair                |
